

Figure 20: Dr. Paul Maslin has sampled juvenile salmonids in many locations in and around the study area. “X”s mark some of the locations sampled; note that some sites may appear as “terrestrial” habitat during times of summer flow, such as that shown here. To the north of the study area, water flowing out of the river during times of flood, flows through the study area, then heads back into the river (indicated with black arrows). This likely accounts for the remnant quality of the area as floodplain habitat for juvenile salmonids and other fish.
